Definition (Monad in functional programming). A monad

⟨return, join, fmap, bind, fish, lift⟩

is a set of operations with the following signature:

```
return: X \to MX

lift: (X \to Y) \to (X \to MY)

fish: (X \to MY) \to (Y \to MZ) \to (X \to MZ)

join: MMX \to MX

fmap: (X \to Y) \to (MX \to MY)

bind: MX \to (X \to MY) \to MY
```

These maps satisfy the equivalent axioms of unitality and associativity:

- > return is a left identity for bind;
- *return* is a right identity for *bind*;
- > bind is associative.
